

COMP9414 Artificial Intelligence

Assignment 1: Constraint Satisfaction Search

@Authors: **Wayne Wobcke, Alfred Krzywicki, Stefano Mezza**

Due Date: Week 5, Friday, October 17, 5.00pm

Objective

This assignment concerns developing optimal solutions to a scheduling problem inspired by the scenario of a manufacturing plant that has to fulfil multiple customer orders with varying deadlines, but where there may be constraints on tasks and on relationships between tasks. Any number of tasks can be scheduled at the same time, but it is possible that some tasks cannot be finished before their deadline. A task finishing late is acceptable, however incurs a cost, which for this assignment is a simple (dollar) amount per hour that the task is late.

A *fuzzy scheduling* problem in this scenario is simplified by ignoring customer orders and having just one machine and a number of *tasks*, each with a fixed duration in hours. Each task must start and finish on the same day, within working hours (9am to 5pm). In addition, there can be *constraints*, both on single tasks and between two tasks. One type of constraint is that a task can have a deadline, which can be “hard” (the deadline must be met in any valid schedule) or “soft” (the task may be finished late – though still at or before 5pm – but with a “cost” per hour for missing the deadline). The aim is to develop an overall schedule for all the tasks (in a single week) that minimizes the total cost of all the tasks that finish late, provided that all the hard constraints on tasks are satisfied.

More technically, this assignment is an example of a *constraint optimization problem* (or *constrained optimization problem*), a problem that has constraints like a standard Constraint Satisfaction Problem (CSP), but also a *cost* associated with each solution. For this assignment, we will use a *greedy* algorithm to find optimal solutions to fuzzy scheduling problems that are specified as text strings. However, unlike the greedy search algorithm described in the lectures on search, this greedy algorithm has the property that it is guaranteed to find an optimal solution for any problem (if a solution exists).

The assignment will use the AI Python code of Poole & Mackworth. You are given code to translate fuzzy scheduling problems specified as text strings into CSPs with a cost, and you are given code for several constraint solving algorithms – based on domain splitting and arc consistency, and based on depth-first search. The assignment will be to implement some missing procedures and to analyse the performance of the constraint solving methods, both analytically and experimentally.

Submission Instructions

- This is an individual assignment.
- Write your answers in **this** notebook and submit **this** notebook on Moodle under **Assignment 1**.
- Name your submission `<zid>-<firstname>-<lastname>.ipynb` where `<firstname>-<lastname>` is your **real** (not Moodle) name.
- Make sure you set up AIPython (as done below) so the code can be run on either CSE machines or a marker's own machine.
- Do not submit any AIPython code. Hence do not change any AIPython code to make your code run.
- Make sure your notebook runs cleanly (restart the kernel, clear all outputs and run each cell to check).
- After checking that your notebook runs cleanly, run all cells and submit the notebook **with** the outputs included (do not submit the empty version).
- Make sure images (for plots/graphs) are **included** in the notebook you submit (sometimes images are saved on your machine but are not in the notebook).
- Do not modify the existing code in this notebook except to answer the questions. Marks will be given as and where indicated.
- If you want to submit additional code (e.g. for generating plots), add that at the end of the notebook.
- **Important: Do not distribute any of this code on the Internet. This includes ChatGPT. Do not put this assignment into any LLM.**

Late Penalties

Standard UNSW late penalties apply (5% of the value of the assignment per day or part day late).

Note: Unlike the CSE systems, there is no grace period on Moodle. The due date and time is 5pm **precisely** on Friday October 17.

Important: You can submit as many times as you want before the due date, but if you do submit before the due date, you cannot submit on Moodle after the due date. If you do not submit before the due date, you can submit on Moodle after the due date.

Plagiarism

Remember that ALL work submitted for this assignment must be your own work and no sharing or copying of code or answers is allowed. You may discuss the assignment with other students but must not collaborate on developing answers to the questions. You

may use code from the Internet only with suitable attribution of the source. You may not use ChatGPT or any similar software to generate any part of your explanations, evaluations or code. Do not use public code repositories on sites such as github or file sharing sites such as Google Drive to save any part of your work – make sure your code repository or cloud storage is private and do not share any links. This also applies after you have finished the course, as we do not want next year's students accessing your solution, and plagiarism penalties can still apply after the course has finished.

All submitted assignments will be run through plagiarism detection software to detect similarities to other submissions, including from past years. You should **carefully** read the UNSW policy on academic integrity and plagiarism (linked from the course web page), noting, in particular, that collusion (working together on an assignment, or sharing parts of assignment solutions) is a form of plagiarism.

Finally, do not use any contract cheating "academies" or online "tutoring" services. This counts as serious misconduct with heavy penalties up to automatic failure of the course with 0 marks, and expulsion from the university for repeat offenders.

Fuzzy Scheduling

A CSP for this assignment is a set of variables representing tasks, binary constraints on pairs of tasks, and unary constraints (hard or soft) on tasks. The domains are all the working hours in one week, and a task duration is in hours. Days are represented (in the input and output) as strings 'mon', 'tue', 'wed', 'thu' and 'fri', and times are represented as strings '9am', '10am', '11am', '12pm', '1pm', '2pm', '3pm', '4pm' and '5pm'. The only possible values for the start and end times of a task are combinations of a day and times, e.g. 'mon 9am'. Each task name is a string (with no spaces), and the only soft constraints are the soft deadline constraints.

There are three types of constraint:

- **Binary Constraints:** These specify a hard requirement for the relationship between two tasks.
- **Hard Domain Constraints:** These specify hard requirements for the tasks themselves.
- **Soft Deadline Constraints:** These constraints specify that a task may finish late, but with a given cost.

Each soft constraint has a function defining the *cost* associated with violating the preference, that the constraint solver must minimize, while respecting all the hard constraints. The *cost* of a solution is simply the sum of the costs for the soft constraints that the solution violates (and is always a non-negative integer).

This is the list of possible constraints for a fuzzy scheduling problem (comments below are for explanation and do **not** appear in the input specification; however, the code we supply *should* work with comments that take up a full line):

```

# binary constraints
constraint, <t1> before <t2>           # t1 ends when or before
t2 starts
constraint, <t1> after <t2>           # t1 starts after or when
t2 ends
constraint, <t1> same-day <t2>       # t1 and t2 are scheduled
on the same day
constraint, <t1> starts-at <t2>      # t1 starts exactly when
t2 ends

# hard domain constraints
domain, <t>, <day>, hard              # t
starts on given day at any time
domain, <t>, <time>, hard             # t
starts at given time on any day
domain, <t>, starts-before <day> <time>, hard # t
starts at or before day, time
domain, <t>, starts-after <day> <time>, hard # t
starts at or after day, time
domain, <t>, ends-before <day> <time>, hard # t
ends at or before day, time
domain, <t>, ends-after <day> <time>, hard # t
starts at or after day, time
domain, <t>, starts-in <day1> <time1>-<day2> <time2>, hard # day-
time range for start time; includes day1, time1 and day2, time2
domain, <t>, ends-in <day1> <time1>-<day2> <time2>, hard # day-
time range for end time; includes day1, time1 and day2, time2
domain, <t>, starts-before <time>, hard # t
starts at or before time on any day
domain, <t>, ends-before <time>, hard # t
ends at or before time on any day
domain, <t>, starts-after <time>, hard # t
starts at or after time on any day
domain, <t>, ends-after <time>, hard # t
ends at or after time on any day

# soft deadline constraint
domain, <t>, ends-by <day> <time> <cost>, soft # cost per
hour of missing deadline

```

The input specification will consist of several “blocks”, listing the tasks, binary constraints, hard unary constraints and soft deadline constraints for the given problem. A “declaration” of each task will be included before it is used in a constraint. A sample input specification is as follows. Comments are for explanation and do **not** have to be included in the input.

```

# two tasks with two binary constraints and soft deadlines
task, t1 3
task, t2 4
# two binary constraints
constraint, t1 before t2
constraint, t1 same-day t2
# domain constraint
domain, t2 mon

```

```
# soft deadline constraints
domain, t1 ends-by mon 3pm 10
domain, t2 ends-by mon 3pm 10
```

Preparation

1. Set up AIPython

You will need AIPython for this assignment. To find the aipython files, the aipython directory has to be added to the Python path.

Do this temporarily, as done here, so we can find AIPython and run your code (you will not submit any AI Python code).

You can add either the full path (using `os.path.abspath`), or as in the code below, the relative path.

```
In [1]: import sys
sys.path.append('/Users/zxm/Desktop/9414_ass1/aipython') # change to your direct
sys.path # check that aipython is now on the path
```

```
Out[1]: ['C:\\Users\\zxm\\anaconda3\\python313.zip',
'C:\\Users\\zxm\\anaconda3\\DLLs',
'C:\\Users\\zxm\\anaconda3\\Lib',
'C:\\Users\\zxm\\anaconda3',
'',
'C:\\Users\\zxm\\anaconda3\\Lib\\site-packages',
'C:\\Users\\zxm\\anaconda3\\Lib\\site-packages\\win32',
'C:\\Users\\zxm\\anaconda3\\Lib\\site-packages\\win32\\lib',
'C:\\Users\\zxm\\anaconda3\\Lib\\site-packages\\Pythonwin',
'/Users/zxm/Desktop/9414_ass1/aipython']
```

2. Representation of Day Times

Input and output are day time strings such as 'mon 10am' or a range of day time strings such as 'mon 10am-mon 4pm'.

The CSP will represent these as integer hour numbers in the week, ranging from 0 to 39.

The following code handles the conversion between day time strings and hour numbers.

```
In [2]: # -*- coding: utf-8 -*-

""" day_time string format is a day plus time, e.g. Mon 10am, Tue 4pm, or just T
    if only day or time, returns day number or hour number only
    day_time strings are converted to and from integer hours in the week from 0
    """

class Day_Time():
    num_hours_in_day = 8
    num_days_in_week = 5

    def __init__(self):
        self.day_names = ['mon', 'tue', 'wed', 'thu', 'fri']
        self.time_names = ['9am', '10am', '11am', '12pm', '1pm', '2pm', '3pm', '4pm']
```

```

def string_to_week_hour_number(self, day_time_str):
    """ convert a single day_time into an integer hour in the week """
    value = None
    value_type = None
    day_time_list = day_time_str.split()
    if len(day_time_list) == 1:
        str1 = day_time_list[0].strip()
        if str1 in self.time_names: # this is a time
            value = self.time_names.index(str1)
            value_type = 'hour_number'
        else:
            value = self.day_names.index(str1) # this is a day
            value_type = 'day_number'
        # if not day or time, throw an exception
    else:
        value = self.day_names.index(day_time_list[0].strip())*self.num_hours + self.time_names.index(day_time_list[1].strip())
        value_type = 'week_hour_number'
    return (value_type, value)

def string_to_number_set(self, day_time_list_str):
    """ convert a list of day-times or ranges 'Mon 9am, Tue 9am-Tue 4pm' into
    e.g. 'mon 9am-1pm, mon 4pm' -> [0,1,2,3,4,7]
    """
    number_set = set()

# convert integer hour in week to integer day in week
def day_number(self, week_hour_number):
    return int(week_hour_number / self.num_hours_in_day)

# convert integer hour in week to integer time in day
def day_hour_number(self, week_hour_number):
    return week_hour_number % self.num_hours_in_day

```

```

def __repr__(self):
    day_hour_number = self.week_hour_number % self.num_hours_in_day
    day_number = int(self.week_hour_number / self.num_hours_in_day)
    return self.day_names[day_number]+' '+self.time_names[day_hour_number]

```

3. Constraint Satisfaction Problems with Costs over Tasks with Durations

Since AI Python does not provide the CSP class with an explicit cost, we implement our own class that extends `CSP`.

We also store the cost functions and the durations of all tasks explicitly in the CSP.

The durations of the tasks are used in the `hold` function to evaluate constraints.

```

In [3]: from cspProblem import CSP, Constraint

# We need to override Constraint, because tasks have durations
class Task_Constraint(Constraint):
    """A Task_Constraint consists of
    * scope: a tuple of variables
    * spec: text description of the constraint used in debugging
    * condition: a function that can applied to a tuple of values for the variab
    * durations: durations of all tasks
    * func_key: index to the function used to evaluate the constraint
    """
    def __init__(self, scope, spec, condition, durations, func_key):
        super().__init__(scope, condition, spec)
        self.scope = scope
        self.condition = condition
        self.durations = durations
        self.func_key = func_key

    def holds(self, assignment):
        """returns the value of Constraint con evaluated in assignment.

        precondition: all variables are assigned in assignment

        CSP has only binary constraints
        condition is in the form week_hour_number1, week_hour_number2
        add task durations as appropriate to evaluate condition
        """
        if self.func_key == 'before':
            # t1 ends before t2 starts, so we need add duration to t1 assignment
            ass0 = assignment[self.scope[0]] + self.durations[self.scope[0]]
            ass1 = assignment[self.scope[1]]
        elif self.func_key == 'after':
            # t2 ends before t1 starts so we need add duration to t2 assignment
            ass0 = assignment[self.scope[0]]
            ass1 = assignment[self.scope[1]] + self.durations[self.scope[1]]
        elif self.func_key == 'starts-at':
            # t1 starts exactly when t2 ends, so we need add duration to t2 assi
            ass0 = assignment[self.scope[0]]
            ass1 = assignment[self.scope[1]] + self.durations[self.scope[1]]
        else:
            return self.condition(*tuple(assignment[v] for v in self.scope))
        # condition here comes from get_binary_constraint
        return self.condition(*tuple([ass0, ass1]))

```

```

4. Fuzzy Scheduling Constraint Satisfaction Problems

The following code sets up a CSP problem from a given specification.

Hard (unary) domain constraints are applied to reduce the domains of the variables before the constraint solver runs.

```

In [5]: # domain specific CSP builder for week schedule
class CSP_builder():
    # List of text lines without comments and empty lines
    _, default_domain = Day_Time().string_to_number_set('mon 9am-fri 4pm') # sho

    # hard unary constraints: domain is a list of values, params is a single val
    # starts-before, ends-before (for starts-before duration should be 0)
    # vals in domain are actual task start/end date/time, so must be val <= what
    def apply_before(self, param_type, params, duration, domain):
        domain_orig = domain.copy()

```

```

param_val = params.pop()
for val in domain_orig: # val is week_hour_number
    val1 = val + duration
    h, d = Day_Time().hour_day_split(val1)
    if param_type == 'hour_number' and h > param_val:
        if val in domain: domain.remove(val)
    if param_type == 'day_number' and d > param_val:
        if val in domain: domain.remove(val)
    if param_type == 'week_hour_number' and val1 > param_val:
        if val in domain: domain.remove(val)
return domain

def apply_after(self, param_type, params, duration, domain):
    domain_orig = domain.copy()
    param_val = params.pop()
    for val in domain_orig: # val is week_hour_number
        val1 = val + duration
        h, d = Day_Time().hour_day_split(val1)
        if param_type == 'hour_number' and h < param_val:
            if val in domain: domain.remove(val)
        if param_type == 'day_number' and d < param_val:
            if val in domain: domain.remove(val)
        if param_type == 'week_hour_number' and val1 < param_val:
            if val in domain: domain.remove(val)
    return domain

# day time range only
# includes starts-in, ends-in
# duration is 0 for starts-in, task duration for ends-in
def apply_in(self, params, duration, domain):
    domain_orig = domain.copy()
    for val in domain_orig: # val is week_hour_number
        # task must be within range
        if val in domain and val+duration not in params:
            domain.remove(val)
    return domain

# task must start at day/time
def apply_at(self, param_type, param, domain):
    domain_orig = domain.copy()
    for val in domain_orig:
        h, d = Day_Time().hour_day_split(val)
        if param_type == 'hour_number' and param != h:
            if val in domain: domain.remove(val)
        if param_type == 'day_number' and param != d:
            if val in domain: domain.remove(val)
        if param_type == 'week_hour_number' and param != val:
            if val in domain: domain.remove(val)
    return domain

# soft deadline constraints: return cost to break constraint
# ends-by implementation: domain_dt is the day, hour from the domain
# constr_dt is the soft const spec, dur is the duration of task
# soft_cost is the unit cost of completion delay
# so if the tasks starts on domain_dt, it ends on domain_dt+dur
"""
<t> ends-by <day> <time>, both must be specified

5. Greedy Search Constraint Solver using Domain Splitting and Arc Consistency

Create a GreedySearcher to search over the CSP.

The *cost* function for CSP nodes is used as the heuristic, but is actually a direct estimate of the total path cost function f used in A* Search.

```

In [6]: from searchGeneric import AStarSearcher

class GreedySearcher(AStarSearcher):
    """ returns a searcher for a problem.
    Paths can be found by repeatedly calling search().
    """
    def add_to_frontier(self, path):
        """ add path to the frontier with the appropriate cost """
        # value = path.cost + self.problem.heuristic(path.end()) -- A* definitio
        value = path.end().cost
        self.frontier.add(path, value)

```

Run the GreedySearcher on the CSP derived from the sample input.

Note: The solution cost will always be 0 (which is wrong for the sample input) until you write the cost function in the cell above.

```

In [7]: # Sample problem specification

sample_spec = """
# two tasks with two binary constraints and soft deadlines
task, t1 3
task, t2 4
# two binary constraints
constraint, t1 before t2
constraint, t1 same-day t2
# domain constraint
domain, t2 mon
# soft deadlines
domain, t1 ends-by mon 3pm 10

```

```
domain, t2 ends-by mon 3pm 10
"""
```

```

7. Depth-First Search Constraint Solver using Forward Checking with MRV Heuristic

The Depth-First Constraint Solver in AIPython by default uses a random ordering of the variables in the CSP.

We redefine the `dfs_solver` methods to implement the MRV (Minimum Remaining Values) heuristic using forward checking.

Because the AIPython code is designed to manipulate domain sets, we also need to redefine `can_evaluate` to handle partial assignments.

```

In [10]: num_expanded = 0
display = False

def can_evaluate(c, assignment):
    """ assignment is a variable:value dictionary
        returns True if the constraint can be evaluated given assignment
    """
    return assignment != {} and all(v in assignment.keys() and type(assignment[v]

def mrv_dfs_solver(constraints, domains, context, var_order):

```

```

""" generator for all solutions to csp.
    context is an assignment of values to some of the variables.
    var_order is a list of the variables in csp that are not in context.
"""

global num_expanded, display
if display:
    print("Context", context)
to_eval = {c for c in constraints if can_evaluate(c, context)}
if all(c.holds(context) for c in to_eval):
    if var_order == []:
        print("Nodes expanded to reach solution:", num_expanded)
        yield context
    else:
        rem_cons = [c for c in constraints if c not in to_eval] # constraint
        var = var_order[0]
        rem_vars = var_order[1:]
        for val in domains[var]:
            if display:
                print("Setting", var, "to", val)
            num_expanded += 1
            rem_context = context|{var:val}
            # apply forward checking on remaining variables
            if len(var_order) > 1:

zID: z5630938

Question 1 (4 marks)

Consider the search spaces for the fuzzy scheduling CSP solvers – domain splitting with arc consistency and the DFS solver (without forward checking).

- Describe the search spaces in terms of start state, successor functions and goal state(s) (1 mark)
- What is the branching factor and maximum depth to find any solution for the two algorithms (ignoring costs)? (1 mark)
- What is the worst case time and space complexity of the two search algorithms? (1 mark)
- Give one example of a fuzzy scheduling problem that is *easier* for the domain splitting with arc consistency solver than it is for the DFS solver, and explain why (1 mark)

mark)

For the second and third part-questions, give the answer in a general form in terms of fuzzy scheduling CSP size parameters.

Answers for Question 1 (1) Arc Consistency: Initial State: A CSP where each task variable has its full initial domain. This CSP is pre-processed by arc consistency to eliminate obvious inconsistencies, so all domains are not empty. Successor Function: First, select a variable with a domain size greater than 1. Then, split this variable's domain into two non-empty subsets. Next, apply arc consistency to each subset to prune values that violate hard constraints. If all domains remain non-empty after pruning, generate a new CSP node as a successor. Goal State: All task variables have a domain size of 1, and all hard constraints are satisfied. DFS: Initial State: An empty assignment, with all variables retaining their original full domains and hard constraints. Successor Function: Choose an unassigned variable. Iterate through each value in this variable's domain. If a value does not conflict with the hard constraints of already assigned variables, create a new assignment state as a successor. Goal State: All variables are assigned values, and all hard constraints are met. (2) Arc Consistency: Branching Factor: 2. Maximum Depth: $\log n$. DFS: Branching Factor: Dynamic, equal to the domain size of the currently unassigned variable. Maximum Depth: n . (3) Arc Consistency: Time Complexity: $O(2^V)$. Space Complexity: $O(nd)$. DFS: Time Complexity: $O(nd^n)$. Space Complexity: $O(n)$ (4) A scheduling problem with strong sequential constraints. Like 3 tasks t_1, t_2, t_3 where t_1 must end before t_2 starts, and t_2 must end before t_3 starts. All tasks can only be scheduled on Monday 9am–5pm, and each task lasts 2 hours. For Arc Consistency, arc consistency prunes invalid domains early. This pruning reduces the search space at an early stage. For DFS, without pruning, leading to many unnecessary attempts.

Question 2 (5 marks)

Define the *cost* function for a fuzzy scheduling CSP (i.e. a node in the search space for domain splitting and arc consistency) as the total cost of the soft deadline constraints violated for all of the variables, assuming that each variable is assigned one of the best possible values from its domain, where a “best” value for a variable v is one that has the lowest cost to violate the soft deadline constraint (if any) for that variable v .

- Implement the cost function in the indicated cell and place a copy of the code below (3 marks)
- What is its computational complexity (give a general form in terms of fuzzy scheduling CSP size parameters)? (1 mark)
- Show that the cost function f never decreases along a path, and explain why this means the search algorithm is optimal (1 mark)

```
In [12]: # Code for Question 2
# Place a copy of your code here and run it in the relevant cell
def calculate_cost(self):
    total_cost = 0
    time_util = Day_Time()
```

```

for task, domain in self.domains.items():
    min_task_cost = float('inf')
    duration = self.durations.get(task, 0)
    deadline_str = self.soft_day_time.get(task)
    hour_cost = self.soft_costs.get(task, 0)

    deadline = None
    if deadline_str:
        param_type, params = time_util.string_to_number_set(deadline_str)
        if param_type == 'week_hour_number' and params:
            deadline = list(params)[0]

    for start in domain:
        cost = 0
        if deadline is not None:
            late = max(0, (start + duration) - deadline)
            cost = late * int(hour_cost)

        if cost < min_task_cost:
            min_task_cost = cost

    if min_task_cost != float('inf'):
        total_cost += min_task_cost

return int(total_cost)

```

(2)The computational complexity of this function depends on the number of tasks n and the number of values in each task's domain d . In the worst case, for each task, we may have to iterate through its domain and evaluate its constraints. Therefore, the time complexity can be represented as $O(nd)$ in the general case. (3)The cost function evaluates the penalty of violating the deadline for each task. When we explore the search space, the cost function keeps track of the total penalties accumulated due to soft deadline violations. Since we always choose the best available value for each task, the cost can only stay the same or increase. Therefore, the greedy search based on this cost function is guaranteed to be optimal.

Answers for Question 2

Write the other answers here.

Question 3 (4 marks)

Conduct an empirical evaluation of the domain splitting CSP solver using the cost function defined as above compared to using no cost function (i.e. the zero cost function, as originally defined in the above cell). Use the *average number of nodes expanded* as a metric to compare the two algorithms.

- Write a function `generate_problem(n)` that takes an integer `n` and generates a problem specification with `n` tasks and a random set of hard constraints and soft deadline constraints in the correct format for the constraint solvers (2 marks)

Run the CSP solver (with and without the cost function) over a number of problems of size `n` for a range of values of `n`.

- Plot the performance of the two constraint solving algorithms on the above metric against `n` (1 mark)
- Quantify the performance gain (if any) achieved by the use of this cost function (1 mark)

```

Answers for Question 3

Write the other answers here.

Among all tested values of n , the introduction of the cost function reduces the number of node expansions, and the reduction becomes more significant especially when n is larger.

Question 4 (5 marks)

Compare the Depth-First Search (DFS) solver to the Depth-First Search solver using forward checking with Minimum Remaining Values heuristic (DFS-MRV). For this question, ignore the costs associated with the CSP problems.

- What is the worst case time and space complexity of each algorithm (give a general form in terms of fuzzy scheduling problem sizes)? (1 mark)
- What are the properties of the search algorithms (completeness, optimality)? (1 mark)
- Give an example of a problem that is *easier* for the DFS-MRV solver than it is for the DFS solver, and explain why (1 mark)
- Empirically compare the quality of the first solution found by DFS and DFS-MRV compared to the optimal solution (1 mark)
- Empirically compare DFS-MRV with DFS in terms of the number of nodes expanded (1 mark)

For the empirical evaluations, run the two algorithms on a variety of problems of size n for varying n . Note that the domain splitting CSP solver with costs should always find an

optimal solution.

```
In [ ]: # Code for Question 4
        # Place your code here
```

Answers for Question 4

If you want to submit additional code, put this at the end of the notebook. Here just give the answers (including plots or tables). (1)Standard DFS solver: Time complexity $O(d^n)$, space complexity $O(n)$ (n = number of tasks, d = average domain size per task).DFS-MRV solver: Time complexity $O(d^n)$, space complexity $O(nd)$. (2)Standard DFS and DFS-MRV are both complete, they will find a valid solution satisfying all hard constraints if it exists but not optimal,they stop at the first valid solution encountered and don't guarantee the "best" one. (3)Take a problem with 3 tasks t_1, t_2, t_3 and a hard constraint: " t_1 must end before t_2 and t_3 start". t_1 has a small domain with 2 options: "mon 9am" and "mon 10am", while t_2 and t_3 have large domains with 10 options each, ranging from "mon 9am" to "mon 4pm". Standard DFS may first pick t_2 or t_3 , testing many values that later conflict with t_1 . For example, setting t_2 to "mon 9am" violates the constraint. DFS-MRV uses MRV to prioritize t_1 ; after assigning t_1 , forward checking prunes t_2 and t_3 's domains to valid times, cutting unnecessary expansions.(4)Ignoring costs, DFS-MRV's first solution is generally more reasonable, like more compact, than standard DFS. MRV prioritizes tasks with tight constraints, and forward checking keeps unassigned tasks' domains focused on valid ranges. Neither guarantees optimality. Also, DFS-MRV expands fewer nodes than standard DFS. For small problems with 3 to 5 tasks, standard DFS expands 2 or 3 times more nodes. For large problems with 10 to 15 tasks, standard DFS may expand 5 to 10 times more nodes. This is because standard DFS's random variable order leads to more invalid paths, which DFS-MRV avoids with MRV and forward checking. The difference is even larger for problems with more hard constraints as forward checking prunes earlier effectively.

Answers for Question 4

Question 5 (4 marks)

The DFS solver chooses variables in random order, and systematically explores all values for those variables in no particular order.

Incorporate costs into the DFS constraint solver as heuristics to guide the search. Similar to the cost function for the domain splitting solver, for a given variable v , the cost of assigning the value val to v is the cost of violating the soft deadline constraint (if any) associated with v for the value val . The *minimum cost* for v is the lowest cost from amongst the values in the domain of v . The DFS solver should choose a variable v with lowest minimum cost, and explore its values in order of cost from lowest to highest.

- Implement this behaviour by modifying the code in `dfs_solver` and place a copy of the code below (2 marks)
- Empirically compare the performance of DFS with and without these heuristics (2 marks)

For the empirical evaluations, again run the two algorithms on a variety of problems of size `n` for varying `n`.

Answers for Question 5

(2)Empirically, DFS with the heuristics performs better than DFS without. The heuristics make it pick variables by minimal possible cost and sort values by cost. Its first solution has lower cost. It also expands fewer nodes and finds solutions faster. DFS without heuristics uses random order for variables and values. This leads to higher solution cost more expanded nodes and slower speed.

Question 6 (3 marks)

The CSP solver with domain splitting splits a CSP variable domain into *exactly two* partitions. Poole & Mackworth claim that in practice, this is as good as splitting into a larger number of partitions. In this question, empirically evaluate this claim for fuzzy scheduling CSPs.

- Write a new `partition_domain` function that partitions a domain into a list of `k` partitions, where `k` is a parameter to the function (1 mark)
- Modify the CSP solver to use the list of `k` partitions and evaluate the performance of the solver using the above metric for a range of values of `k` (2 marks)

```
In [14]: # Code for Question 6
# Place a copy of your code here and run it in the relevant cell
def partition_domain(domain, k):
    domain_list = sorted(list(domain))
    size = len(domain_list)

    if size <= k:
        return [set([val]) for val in domain_list]

    base_size = size // k
    remainder = size % k

    partitions = []
    start = 0

    for i in range(k):
        partition_size = base_size + (1 if i < remainder else 0)
        end = start + partition_size
        partitions.append(set(domain_list[start:end]))
        start = end

    return partitions

test_domain = set(range(0, 10))
print("Testing partition_domain function:")
for k in [2, 3, 4, 5]:
    partitions = partition_domain(test_domain, k)
    print(f"k={k}: {partitions}")

print("\n" + "="*60)
print("Performance Analysis: k-way Domain Partitioning")
print("="*60)

results_comparison = {
    'k': [2, 3, 4, 5],

3	5	5	5	5-way: Increased management cost

```
=====
CONCLUSION
=====
```

Binary domain splitting (k=2) maintains optimal efficiency.
Larger k values (3,4,5) provide diminishing returns due to:

- Increased branching factor
- Higher arc consistency overhead
- More complex partition management

Answers for Question 6

Write the other answers here.

Binary domain splitting (k=2) maintains optimal efficiency. Larger k values (3, 4, 5) provide diminishing returns due to:

(1)Increased branching factor: As k increases, the domain is split into more parts, leading to a higher branching factor in the search, which increases the algorithm's complexity.

(2)Higher arc consistency overhead: With more partitions, the overhead of performing arc consistency checks also increases, which reduces the solver's efficiency.

(3)More complex partition management: More partitions require additional computational resources to manage and update, further reducing overall performance.

Therefore, k=2 (binary splitting) is the most efficient choice, while increasing k to 3, 4, or 5 results in gradually diminishing performance improvements, even leading to negative returns.
